50MHz Current Feedback Amplifier

élantec

The EL2020 is a fast settling, wide bandwidth amplifier optimized for gains between -10 and +10. Built using the Elantec monolithic Complementary Bipolar process, this amplifier uses current mode feedback to achieve more bandwidth at a given gain then a conventional voltage feedback operational amplifier.

The EL2020 will drive two double terminated 75Ω coax cables to video levels with low distortion. Since it is a closed loop device, the EL2020 provides better gain accuracy and lower distortion than an open loop buffer. The device includes output short circuit protection, and input offset adjust capability.

The bandwidth and slew rate of the EL2020 are relatively independent of the closed loop gain taken. The 50MHz bandwidth at unity gain only reduces to 30MHz at a gain of 10. The EL2020 may be used in most applications where a conventional op amp is used, with a big improvement in speed power product.

Ordering Information

PART NUMBER	TEMP. RANGE	PACKAGE	PKG. NO.
EL2020CN	-40°C to +85°C	8-Pin PDIP	MDP0031
EL2020CM	-40°C to +85°C	20-Pin SOL	MDP0027
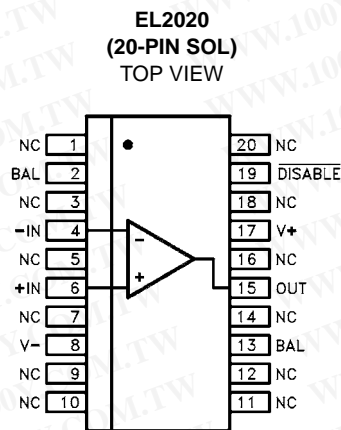

Features

- Slew rate 500V/μs
- ±33mA output current
- Drives ±2.4V into 75Ω
- Differential phase < 0.1°
- Differential gain < 0.1%
- V supply ±5V to ±18V
- Output short circuit protected
- Uses current mode feedback
- 1% settling time of 50ns for 10V step
- Low cost
- 9mA supply current
- 8-pin mini-dip

Applications

- Video gain block
- Residue amplifier
- Radar systems
- Current to voltage converter
- Coax cable driver with gain of 2

Application Information

Theory of Operation

The EL2020 has a unity gain buffer similar to the EL2003 from the non-inverting input to the inverting input. The error signal of the EL2020 is a current flowing into (or out of) the inverting input. A very small change in current flowing through the inverting input will cause a large change in the output voltage. This current amplification is the transresistance (R_{OL}) of the EL2020 [$V_{OUT} = R_{OL} * I_{INV}$]. Since R_{OL} is very large (≈ 106), the current flowing into the inverting input in the steady state (non-slewing) condition is very small.

Therefore we can still use op-amp assumptions as a first order approximation for circuit analysis, namely that...

1. The voltage across the inputs ≈ 0 and
2. The current into the inputs is ≈ 0
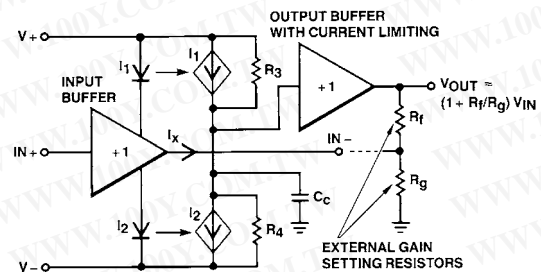

**SIMPLIFIED BLOCK DIAGRAM OF EL2020**

Resistor Value Selection and Optimization

The value of the feedback resistor (and an internal capacitor) sets the AC dynamics of the EL2020. A nominal value for the feedback resistor is 1kΩ, which is the value used for production testing. This value guarantees stability. For a given gain, the bandwidth may be increased by decreasing the feedback resistor and, conversely, the bandwidth will be decreased by increasing the feedback resistor.

Reducing the feedback resistor too much will result in overshoot and ringing, and eventually oscillations. Increasing the feedback resistor results in a lower -3dB frequency. Attenuation at high frequency is limited by a zero in the closed loop transfer function which results from stray capacitance between the inverting input and ground.

Power Supplies

The EL2020 may be operated with single or split power supplies as low as ±3V (6V total) to as high as ±18V (36V total). The slew rate degrades significantly for supply voltages less than ±5V (10V total), but the bandwidth only changes 25% for supplies from ±3V to ±18V. It is not necessary to use equal value split power supplies, i.e., -5V and +12V would be excellent for 0V to 1V video signals. Bypass capacitors from each supply pin to a ground plane are recommended. The EL2020 will not oscillate even with minimal bypassing, however, the supply will ring excessively with inadequate capacitance. To eliminate supply ringing and the errors it might cause, a 4.7µF tantalum capacitor with short leads is recommended for both supplies. Inadequate supply bypassing can also result in lower slew rate and longer settling times.
NON-INVERTING AMPLIFIER

-5	680Ω	130Ω	40MHz	55ns	160ns
-10	680Ω	68Ω	3MHz	70ns	170ns

Input Range

The non-inverting input to the EL2020 looks like a high resistance in parallel with a few picofarads in addition to a DC bias current. The input characteristics change very little with output loading, even when the amplifier is in current limit.

The input characteristics also change when the input voltage exceeds either supply by 0.5V. This happens because the input transistor's base-collector junctions forward bias. If the input exceeds the supply by LESS than 0.5V and then returns to the normal input range, the output will recover in less than 10ns. However if the input exceeds the supply by MORE than 0.5V, the recovery time can be 100s of nanoseconds. For this reason it is recommended that Schottky diode clamps from input to supply be used if a fast recovery from large input overloads is required.

Source Impedance

The EL2020 is fairly tolerant of variations in source impedances. Capacitive sources cause no problems at all, resistive sources up to 100kΩ present no problems as long as care is used in board layout to minimize output to input coupling. Inductive sources may cause oscillations; a 1kΩ resistor in series with the input lead will usually eliminate problems without sacrificing too much speed.

Current Limit

The EL2020 has internal current limits that protect the output transistors. The current limit goes down with junction temperature rise. At a junction temperature of +175°C the current limits are at about 50mA. If the EL2020 output is shorted to ground when operating on ±15V supplies, the power dissipation could be as great as 1.1W. A heat sink is required in order for the EL2020 to survive an indefinite short. Recovery time to come out of current limit is about 50ns.

Using the EL2020 with Output Buffers

When more output current is required, a wideband buffer amplifier can be included in the feedback loop of the EL2020. With the EL2003 the subsystem overshoots about 10% due to the phase lag of the EL2003. With the EL2004 in the loop, the overshoot is less than 2%. For even more output current, several buffers can be paralleled.
EL2020 BUFFERED WITH AN EL2004

Capacitive Loads

The EL2020 is like most high speed feedback amplifiers in that it does not like capacitive loads between 50pF and 1000pF. The output resistance works with the capacitive load to form a second non-dominate pole in the loop. This results in excessive peaking and overshoot and can lead to oscillations. Standard resistive isolation techniques used with other op amps work well to isolate capacitive loads from the EL2020.

Offset Adjust

To calculate the amplifier system offset voltage from input to output we use the equation:

Output Offset Voltage = V_{OS} (R_F/R_G+1) ± I_{BIAS} (R_F)

The EL2020 output offset can be nulled by using a 10kΩ potentiometer from pins 1 to 5 with the slider tied to pin 7 (+V_{CC}). This adjusts both the offset voltage and the inverting input bias current. The typical adjustment range is ±80mV at the output.

Compensation

The EL2020 is internally compensated to work with external feedback resistors for optimum bandwidth over a wide range of closed loop gain. The part is designed for a nominal 1kΩ of feedback resistance, although it is possible to get more bandwidth by decreasing the feedback resistance.

The EL2020 becomes less stable by adding capacitance in parallel with the feedback resistor, so feedback capacitance is not recommended.

The EL2020 is also sensitive to stray capacitance from the inverting input to ground, so the board should be laid out to keep the physical size of this node small, with ground plane kept away from this node.

Active Filters

The EL2020's low phase lag at high frequencies makes it an excellent choice for high performance active filters. The filter response more closely approaches the theoretical response than with conventional op amps due to the EL2020's smaller propagation delay. Because the internal compensation of the EL2020 depends on resistive feedback, the EL2020 should be set up as a gain block.

Driving Cables

The EL2020 was designed with driving coaxial cables in mind. With 30mA of output drive and low output impedance, driving one to three 75Ω double terminated coax cables with one EL2020 is practical. Since it is easy to set up a gain of +2, the double matched method is the best way to drive coax cables, because the impedance match on both ends of the cable will suppress reflections. For a discussion on some of the other ways to drive cables, see the section on driving cables in the EL2003 data sheet.

Video Performance Characteristics

The EL2020 makes an excellent gain block for video systems, both RS-170 (NTSC) and faster. It is capable of driving 3 double terminated 75Ω cables with distortion levels acceptable to broadcasters. A common video application is to drive a 75Ω double terminated coax with a gain of 2.

To measure the video performance of the EL2020 in the non-inverting gain of 2 configuration, 5 identical gain-of-two circuits were cascaded (with a divide by two 75Ω attenuator between each stage) to increase the errors.

The results, shown in the photos, indicate the entire system of 5 gain-of-two stages has a differential gain of 0.5% and a differential phase of 0.5°. This implies each device has a

differential gain/phase of 0.1% and 0.1°, but these are too small to measure on single devices.
DIFFERENTIAL PHASE OF 5 CASCADED GAIN-OF-TWO STAGES

DIFFERENTIAL PHASE OF 5 CASCADED GAIN-OF-TWO STAGES

Video Distribution Amplifier

The distribution amplifier shown below features a difference input to reject common mode signals on the 75Ω coax cable input. Common mode rejection is often necessary to help to eliminate 60Hz noise found in production environments.
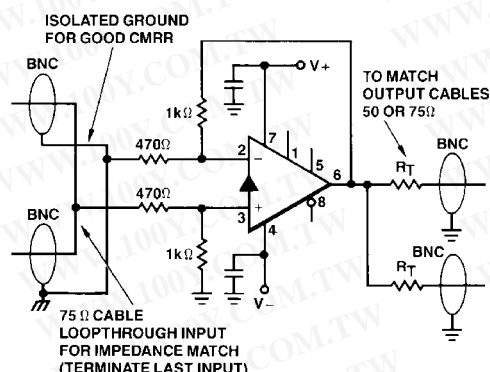

VIDEO DISTRIBUTION AMPLIFIER WITH DIFFERENCE INPUT

EL2020 Disable/Enable Operation

The EL2020 has an enable/disable control input at pin 8. The device is enabled and operates normally when pin 8 is left open or returned to pin 7, V_{CC}. When more than 250µA is pulled from pin 8, the EL2020 is disabled. The output becomes a high impedance, the inverting input is no longer driven to the positive input voltage, and the supply current is halved. To make it easy to use this feature, there is an internal resistor to limit the current to a safe level (~1.1mA) if pin 8 is grounded.

To draw current out of pin 8 an "open collector output" logic gate or a discrete NPN transistor can be used. This logic interface method has the advantage of level shifting the logic signal from 5V supplies to whatever supply the EL2020 is operating on without any additional components.

Using the EL2020 as a Multiplexer

An interesting use of the enable feature is to combine several amplifiers in parallel with their outputs common. This combination then acts similar to a MUX in front of an amplifier. A typical circuit is shown.

When the EL2020 is disabled, the DC output impedance is very high, over 10kΩ. However there is also an output capacitance that is non-linear. For signals of less than 5V peak to peak, the output capacitance looks like a simple 15pF capacitor. However, for larger signals the output capacitance becomes much larger and non-linear.

The example multiplexer will switch between amplifiers in 5µs for signals of less than ±2V on the outputs. For full output signals of 20V peak to peak, the selection time becomes 25µs. The disabled outputs also present a capacitive load and therefore only three amplifiers can have their outputs shorted together. However an unlimited number can sum together if a small resistor (25Ω) is inserted in series with each output to isolate it from the "bus". There will be a small gain loss due to the resistors of course.
