### Introduction

The HAH1BV family is for the electronic measurement of DC, AC or pulsed currents in high power automotive applications with galvanic isolation between the primary circuit (high power) and the secondary circuit (electronic circuit).

The HAH1BV family gives you the choice of having different current measuring ranges in the same housing (from  $\pm 200$  A up to  $\pm 900$  A).

### Features

- Open Loop transducer using the Hall effect
- Unipolar + 5 V DC power supply
- Primary current measuring range up to  $\pm 500$  A
- Maximum rms primary current limited by the busbar, the magnetic core or the ASIC temperature  $T^\circ < + 150^\circ\text{C}$
- Operating temperature range:  $- 40^\circ\text{C} < T^\circ < + 125^\circ\text{C}$
- Output voltage: full ratiometric (in sensitivity and offset)
- Compact design.

### Advantages

- Excellent accuracy
- Very good linearity
- Very low thermal offset drift
- Very low thermal sensitivity drift
- Wide frequency bandwidth
- No insertion losses.

### Automotive applications

- Battery monitoring
- Starter Generators
- Inverters
- HEV application
- EV application.

### Principle of HAH1BV Family

The open loop transducers use an Hall effect integrated circuit.

The magnetic flux density **B**, contributing to the rise of the Hall voltage, is generated by the primary current  $I_p$  to be measured.

The current to be measured  $I_p$  is supplied by a current source i.e. battery or generator (Fig. 1).

Within the linear region of the hysteresis cycle, **B** is proportional to:

$$B(I_p) = \text{constant}(a) \times I_p$$

The Hall voltage is thus expressed by:

$$V_H = (R_H/d) \times l \times \text{constant}(a) \times I_p$$

Except for  $I_p$ , all terms of this equation are constant. Therefore:

$$V_H = \text{constant}(b) \times I_p$$

The measurement signal  $V_H$  amplified to supply the user output voltage or current.

Fig. 1: Principle of the open loop transducer

### Dimensions HAH1BV family (in mm. 1mm = 0.0394 inch)

- Plastic case PBT GF 30
- Magnetic core Iron silicon alloy
- Pins Brass tin plated
- Mass 39 g

- $V_{OUT} > \frac{V_C}{2}$  when  $I_P$  flows in the direction of the arrow.

**R<sub>i</sub> > 10 kΩ optional resistor for signal line diagnostic**

| $V_{OUT}$    | Diagnosis      |
|--------------|----------------|
| Open circuit | $V_{IN} = V_C$ |
| Short GND    | $V_{IN} = 0V$  |

**C<sub>L</sub>** < 100 nF EMC protection  
**RC** Low pass filter EMC protection (optional)

## System architecture

## HAH1BV S/02

### Absolute maximum ratings

- Notes:** <sup>1)</sup> Busbar temperature must be below  $150^\circ\text{C}$ .  
<sup>2)</sup> The output voltage  $V_{OUT}$  is fully ratiometric. The offset and sensitivity are dependent on the supply voltage  $V_C$  relative to the following formula:

$$I_P = \left( V_{OUT} - \frac{V_C}{2} \right) \times \frac{1}{G} \times \frac{5}{V_C} \quad \text{with } G \text{ in } (\text{V/A})$$

## HAH1BV S/02

### PERFORMANCES PARAMETERS DEFINITIONS

#### Output noise voltage:

The output voltage noise is the result of the noise floor of the Hall elements and the linear  $I_c$  amplifier gain.

#### Magnetic offset:

The magnetic offset is the consequence of an over-current on the primary side. It's defined after an excursion of  $I_{p\max}$ .

#### Linearity:

The maximum positive or negative discrepancy with a reference straight line  $V_{OUT} = f(I_p)$ .

Unit: linearity (%) expressed with full scale of  $I_{p\max}$ .

Linearity is measured on cycle +  $I_p$ , 0, -  $I_p$ , 0, +  $I_p$  without magnetic offset (average values used)

#### Response time (delay time) $t_r$ :

The time between the primary current signal and the output signal reach at 90 % of its final value

#### Typical:

Theoretical value or usual accuracy recorded during the production.

#### Sensitivity:

The Transducer's sensitivity  $G$  is the slope of the straight line

$V_{out} = f(I_p)$ , it must establish the relation:

$$V_{out}(I_p) = V_c/5 (G \times I_p + 2.5) (*)$$

(\*) For all symetrics transducers.

#### Offset with temperature:

The error of the offset in the operating temperature is the variation of the offset in the temperature considered with the initial offset at 25°C.

The offset variation  $I_{OT}$  is a maximum variation the offset in the temperature range:

$$I_{OT} = I_{OE\max} - I_{OE\min}$$

The Offset drift  $TCI_{OEAV}$  is the  $I_{OT}$  value divided by the temperature range.

#### Sensitivity with temperature:

The error of the sensitivity in the operating temperature is the relative variation of sensitivity with the temperature considered with the initial offset at 25°C.

The sensitivity variation  $G_T$  is the maximum variation (in ppm or %) of the sensitivity in the temperature range:

$$G_T = (Sensitivity\ max - Sensitivity\ min) / Sensitivity\ at\ 25^\circ C.$$

The sensitivity drift  $TCG_{AV}$  is the  $G_T$  value divided by the temperature range.

#### Offset voltage @ $I_p = 0$ A:

Is the output voltage when the primary current is null. The ideal value of  $V_o$  is  $V_c/2$  at  $V_c = 5$  V. So, the difference of  $V_o - V_c/2$  is called the total offset voltage error. This offset error can be attributed to the electrical offset (due to the resolution of the ASIC quiescent voltage trimming), the magnetic offset, the thermal drift and the thermal hysteresis.

#### Environmental test specifications
