8-Bit high-speed multiplying D/A converter — DAC08 Series

DESCRIPTION

The DAC08 series of 8-bit monolithic multiplying Digital-to-Analog Converters provide very high-speed performance coupled with low cost and outstanding applications flexibility.

Advanced circuit design achieves 70ns settling times with very low glitch and at low power consumption. Monotonic multiplying performance is attained over a wide 20-to-1 reference current range. Matching to within 1 LSB between reference and full-scale currents eliminates the need for full-scale trimming in most applications. Direct interface to all popular logic families with full noise immunity is provided by the high swing, adjustable threshold logic inputs.

Dual complementary outputs are provided, increasing versatility and enabling differential operation to effectively double the peak-to-peak output swing. True high voltage compliance outputs allow direct output voltage conversion and eliminate output op amps in many applications.

All DAC08 series models guarantee full 8-bit monotonicity and linearities as tight as 0.1% over the entire operating temperature range. Device performance is essentially unchanged over the ±4.5V to ±18V power supply range, with 37mW power consumption attainable at ±5V supplies.

The compact size and low power consumption make the DAC08 attractive for portable and military aerospace applications.

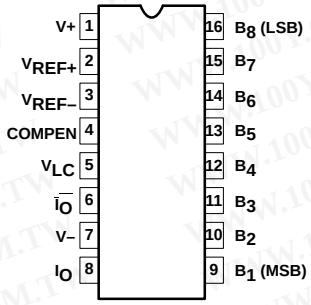
D[1] Package



TOP VIEW

NOTE:
1. SO and non-standard pinouts.

FEATURES

- Fast settling output current—70ns
- Full-scale current prematched to ±1 LSB
- Direct interface to TTL, CMOS, ECL, HTL, PMOS
- Relative accuracy to 0.1% maximum over temperature range
- High output compliance -10V to +18V
- True and complemented outputs
- Wide range multiplying capability
- Low FS current drift — ±10ppm/°C
- Wide power supply range—±4.5V to ±18V
- Low power consumption—37mW at ±5V

APPLICATIONS

- 8-bit, 1µs A-to-D converters
- Servo-motor and pen drivers
- Waveform generators
- Audio encoders and attenuators
- Analog meter drivers
- Programmable power supplies
- CRT display drivers
- High-speed modems
- Other applications where low cost, high speed and complete input/output versatility are required
- Programmable gain and attenuation
- Analog-Digital multiplication

8-Bit high-speed multiplying D/A converter DAC08 Series

FUNCTIONAL DESCRIPTION

Reference Amplifier Drive and Compensation

The reference amplifier input current must always flow into Pin 14 regardless of the setup method or reference supply voltage polarity.

Connections for a positive reference voltage are shown in Figure 1. The reference voltage source supplies the full reference current. For bipolar reference signals, as in the multiplying mode, R_{15} can be tied to a negative voltage corresponding to the minimum input level. R_{15} may be eliminated with only a small sacrifice in accuracy and temperature drift.

The compensation capacitor value must be increased as R_{14} value is increased. This is in order to maintain proper phase margin. For R_{14} values of 1.0, 2.5, and 5.0kΩ, minimum capacitor values are 15, 37, and 75pF, respectively. The capacitor may be tied to either V_{EE} or ground, but using V_{EE} increases negative supply rejection. (Fluctuations in the negative supply have more effect on accuracy than do any changes in the positive supply.)

A negative reference voltage may be used if R_{14} is grounded and the reference voltage is applied to R_{15} as shown. A high input impedance is the main advantage of this method. The negative reference voltage must be at least 3.0V above the V_{EE} supply. Bipolar input signals may be handled by connecting R_{14} to a positive reference voltage equal to the peak positive input level at Pin 15.

When using a DC reference voltage, capacitive bypass to ground is recommended. The 5.0V logic supply is not recommended as a reference voltage, but if a well regulated 5.0V supply which drives logic is to be used as the reference, R_{14} should be formed of two series resistors with the junction of the two resistors bypassed with 0.1µF to ground. For reference voltages greater than 5.0V, a clamp diode is recommended between Pin 14 and ground.

If Pin 14 is driven by a high impedance such as a transistor current source, none of the above compensation methods applies and the amplifier must be heavily compensated, decreasing the overall bandwidth.

Output Voltage Range

The voltage at Pin 4 must always be at least 4.5V more positive than the voltage of the negative supply (Pin 3) when the reference current is 2mA or less, and at least 8V more positive than the negative supply when the reference current is between 2mA and 4mA. This is necessary to avoid saturation of the output transistors, which would cause serious accuracy degradation.

Output Current Range

Any time the full-scale current exceeds 2mA, the negative supply must be at least 8V more negative than the output voltage. This is due to the increased internal voltage drops between the negative supply and the outputs with higher reference currents.

Accuracy

Absolute accuracy is the measure of each output current level with respect to its intended value, and is dependent upon relative accuracy, full-scale accuracy and full-scale current drift. Relative accuracy is the measure of each output current level as a fraction of the full-scale current after zero-scale current has been nulled out. The relative accuracy of the DAC08 series is essentially constant over the operating temperature range due to the excellent temperature tracking of the monolithic resistor ladder. The reference current may drift with temperature, causing a change in the absolute accuracy of output current. However, the DAC08 series has a very low full-scale current drift over the operating temperature range.

The DAC08 series is guaranteed accurate to within ± LSB at +25°C at a full-scale output current of 1.992mA. The relative accuracy test circuit is shown in Figure 1. The 12-bit converter is calibrated to a full-scale output current of 1.99219mA, then the DAC08 full-scale current is trimmed to the same value with R_{14} so that a zero value appears at the error amplifier output. The counter is activated and the error band may be displayed on the oscilloscope, detected by comparators, or stored in a peak detector.

Two 8-bit D-to-A converters may not be used to construct a 16-bit accurate D-to-A converter. 16-bit accuracy implies a total of ± part in 65,536, or ±0.00076%, which is much more accurate than the ±0.19% specification of the DAC08 series.

Monotonicity

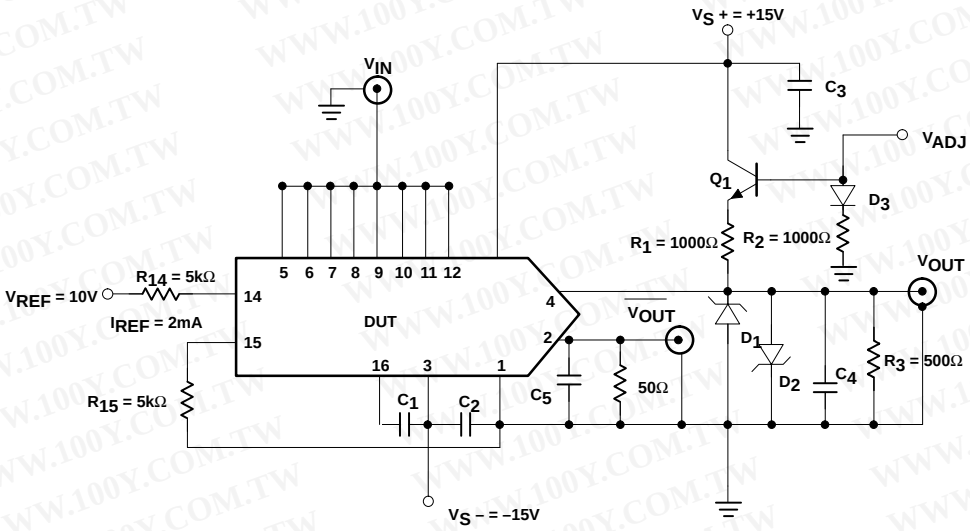
A monotonic converter is one which always provides analog output greater than or equal to the preceding value for a corresponding increment in the digital input code. The DAC08 series is monotonic for all values of reference current above 0.5mA. The recommended range for operation is a DC reference current between 0.5mA and 4.0mA.

Settling Time

The worst-case switching condition occurs when all bits are switched on, which corresponds to a low-to-high transition for all input bits. This time is typically 70ns for settling to within LSB for 8-bit accuracy. This time applies when R_L<500Ω and C_O<25pF. The slowest single switch is the least significant bit, which typically turns on and settles in 65ns. In applications where the DAC functions in a positive-going ramp mode, the worst-case condition does not occur and settling times less than 70ns may be realized.

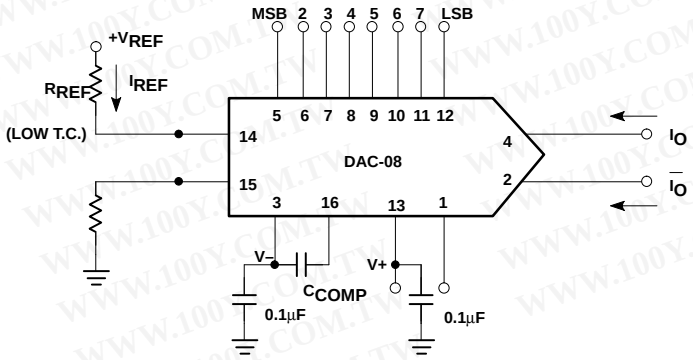
Extra care must be taken in board layout since this usually is the dominant factor in satisfactory test results when measuring settling time. Short leads, 100µF supply bypassing for low frequencies, minimum scope lead length, and avoidance of ground loops are all mandatory.

SETTLING TIME AND PROPAGATION DELAY



NOTES:
D_1, D_2 = IN6263 or equivalent
D_3 = IN914 or equivalent
C_1 = 0.01µF
C_2, C_3 = 0.1µF
Q_1 = 2N3904
C_4, C_5 = 15pF and includes all probe and fixturing capacitance.

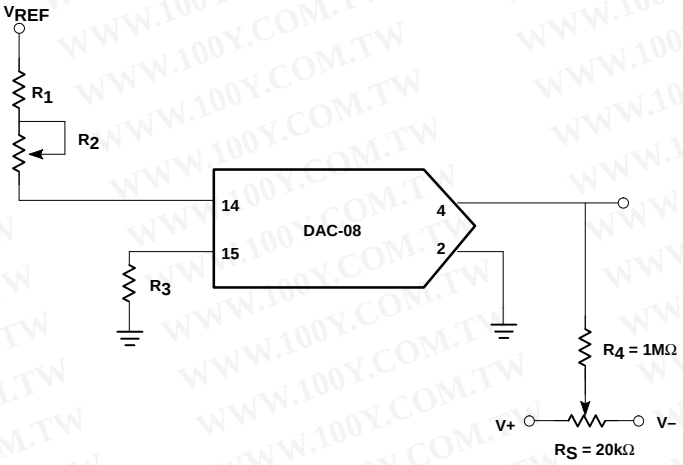
BASIC DAC08 CONFIGURATION



NOTES:

$$I_{FS} \approx \frac{+V_{REF}}{R_{REF}} \times \frac{255}{256} \; ; \; I_O + \overline{I_O} = I_{FS} \text{ for all logic states}$$

RECOMMENDED FULL-SCALE AND ZERO-SCALE ADJUST



NOTES:
R_1 = low T.C.
$R_3 = R_1 + R_2$
$R_2 \approx 0.1\ R_1$ to minimize pot. contribution to full-scale drift
