**Note 4:** For a power supply of  $5V \pm 10\%$  the worst-case output voltages ( $V_{OH}, V_{OL}$ ) occur for HC at 4.5V. Thus the 4.5V values should be used when designing with this supply. Worst-case  $V_{IH}$  and  $V_{IL}$  occur at  $V_{CC} = 5.5V$  and 4.5V respectively. (The  $V_{IH}$  value at 5.5V is 3.85V.) The worst-case leakage current ( $I_{IN}, I_{CC}$ , and  $I_{OZ}$ ) occur for CMOS at the higher voltage and so the 6.0V values should be used.

## Theory of Operation

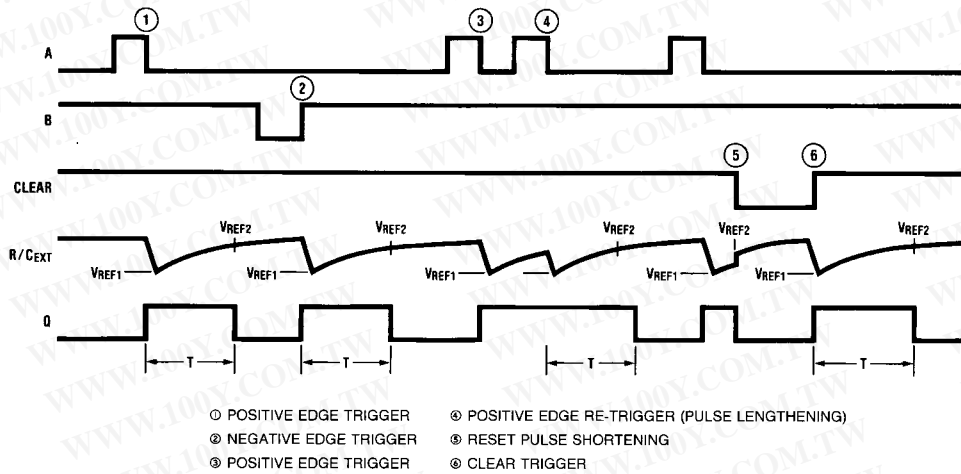

FIGURE 1.

### Trigger Operation

As shown in Figure 1 and the logic diagram, before an input trigger occurs, the one shot is in the quiescent state with the Q output LOW, and the timing capacitor  $C_{EXT}$  completely charged to  $V_{CC}$ . When the trigger input A goes from  $V_{CC}$  to GND (while inputs B and clear are held to  $V_{CC}$ ) a valid trigger is recognized, which turns on comparator C1 and Nchannel transistor N11. At the same time the output latch is set. With transistor N1 on, the capacitor  $C_{EXT}$  rapidly discharges toward GND until  $V_{REF1}$  is reached. At this point the output of comparator C1 changes state and transistor N1 turns off. Comparator C1 then turns off while at the same time comparator C2 turns on. With transistor N1 off, the capacitor  $C_{EXT}$  begins to charge through the timing resistor,  $R_{EXT}$ , toward  $V_{CC}$ . When the voltage across  $C_{EXT}$  equals  $V_{REF2}$ , comparator C2 changes state causing the output latch to reset (Q goes LOW) while at the same time disabling comparator C2. This ends the timing cycle with the monostable in the quiescent state, waiting for the next trigger.

A valid trigger is also recognized when trigger input B goes from GND to  $V_{CC}$  (while input A is at GND and input clear is at  $V_{CC}$ ). The MM74HC123A can also be triggered when clear goes from GND to  $V_{CC}$  (while A is at GND and B is at  $V_{CC}$ ).

It should be noted that in the quiescent state  $C_{EXT}$  is fully charged to  $V_{CC}$  causing the current through resistor  $R_{EXT}$  to be zero. Both comparators are "off" with the total device current due only to reverse junction leakages. An added feature of the MM74HC123A is that the output latch is set via the input trigger without regard to the capacitor voltage. Thus, propagation delay from trigger to Q is independent of the value of  $C_{EXT}$ ,  $R_{EXT}$ , or the duty cycle of the input waveform.

### Retrigger Operation

The MM74HC123A is retriggered if a valid trigger occurs 3 followed by another trigger 4 before the Q output has returned to the quiescent (zero) state. Any retrigger, after the timing node voltage at the R/ $C_{EXT}$  pin has begun to rise from  $V_{REF1}$ , but has not yet reached  $V_{REF2}$ , will cause an increase in output pulse width T. When a valid retrigger is initiated 4, the voltage at the R/ $C_{EXT}$  pin will again drop to  $V_{REF1}$  before progressing along the RC charging curve toward  $V_{CC}$ . The Q output will remain HIGH until time T, after the last valid retrigger.

Because the trigger-control circuit flip-flop resets shortly after  $C_X$  has discharged to the reference voltage of the lower reference circuit, the minimum retrigger time,  $t_{rr}$  is a function of internal propagation delays and the discharge time of  $C_X$ :

$$t_{rr} \approx 20 + \frac{187}{V_{CC} - 0.7} + \frac{565 + (0.256 V_{CC}) C_X}{[V_{CC} - 0.7]^2}$$

Another removal/retrigger time occurs when a short clear pulse is used. Upon receipt of a clear, the one shot must charge the capacitor up to the upper trip point before the one shot is ready to receive the next trigger. This time is dependent on the capacitor used and is approximately:

$$t_{rr} = 196 + \frac{640}{V_{CC} - 0.7} + \frac{522 + (0.3 V_{CC}) C_X}{(V_{CC} - 0.7)^2} \text{ ns}$$

## Theory of Operation (Continued)

### Reset Operation

These one shots may be reset during the generation of the output pulse. In the reset mode of operation, an input pulse on clear sets the reset latch and causes the capacitor to be fast charged to  $V_{CC}$  by turning on transistor Q1 5. When the voltage on the capacitor reaches  $V_{REF2}$ , the reset latch will clear and then be ready to accept another pulse. If the

clear input is held low, any trigger inputs that occur will be inhibited and the Q and  $\bar{Q}$  outputs of the output latch will not change. Since the Q output is reset when an input low level is detected on the Clear input, the output pulse T can be made significantly shorter than the minimum pulse width specification.
